# NACO FORMATION

LATE CARBONIFEROUS PENNSYLVANIAN EPOCH (Desmoinesian to Virgilian), 310 to 304 Million Years Ago

millions of years ago

LITHOLOGY: Limestone, shale, sandstone; medium-gray

Corals, brachiopods, bryozoans, crinoids, fusulinids

#### SEDIMENTARY STRUCTURES:

Horizontal

bedding

## DEPOSITIONAL

**ENVIRONMENT:** Shallow marine shelf, near shoreline to east against Defiance-Zuni positive area

#### PALEOGEOGRAPHY/ TECTONIC SETTING: Continental shelf,

out against Defiance-

Zuni positive area to

platform; wedges

the east

**MISCELLANEOUS:** Correlated with the Horquilla Limestone by Ross, 1973

Geologists examine a Naco Formation outcrop at Carrizo Creek, Arizona

Generalized environments across Arizona during the Pennsylvanian Epoch, the time of deposition of the Naco Formation (modified from Ross, 1991, Blakey and Knepp, 1989)

During the late Carboniferous Period (Pennsylvanian Epoch), the continents of the world began to collide into what would become the supercontinent, Pangaea. The period was marked by multiple cycles of rising and falling sea levels. These sea-level fluctuations were triggered, in turn, by glacial cycles in the Southern Hemisphere. The glaciers stored huge amounts of freshwater during periods of cooling—causing sea levels to drop—then released the water into the seas during warmer periods of melting, causing sea levels to rise. The shallow marine environments of this time, such as existed on the Colorado Plateau, featured an abundance of creatures such as crinoids, brachiopods, and fusilinids. At death, their calcium-rich shells were deposited in lime mud on the ocean floor, which eventually became limestone.

### Fusulinids—Complexity at a Tiny Scale

Fusulinids were small single-celled marine organisms, typically about the size of a grain of wheat, although some forms were over two inches long. The earliest record of fusulinids occurs 320 million years ago. They evolved rapidly, changing into many forms, which make them excellent index fossils in Pennsylvanian rocks such as the Naco Formation. They became extinct during the mass extinction at the end of the Permian Period, about 251 million years ago.

Single-celled organisms rely on one cell to do all the essential life functions—movement, eating, digestion, reproduction, etc. In this way, they are different from multi-cellular life forms, which have various cells with specialized roles.

In order to accommodate all of these functions, the cell of organisms such as fusilinids is very complex. This can be seen in the hard calcium carbonate shells of fusilinids, which are internally divided into a series of chambers.
